

NAME**devname** - get device name**LIBRARY**

Standard C Library (libc, -lc)

SYNOPSIS

```
#include <sys/stat.h>
#include <stdlib.h>
```

```
char *
devname(dev_t dev, mode_t type);
```

```
char *
devname_r(dev_t dev, mode_t type, char *buf, int len);
```

```
char *
fdevname(int fd);
```

```
char *
fdevname_r(int fd, char *buf, int len);
```

DESCRIPTION

The **devname()** function returns a pointer to the name of the block or character device in */dev* with a device number of *dev*, and a file type matching the one encoded in *type* which must be one of S_IFBLK or S_IFCHR. To find the right name, **devname()** asks the kernel via the *kern.devname* sysctl. If it is unable to come up with a suitable name, it will format the information encapsulated in *dev* and *type* in a human-readable format.

The **fdevname()** and **fdevname_r()** function obtains the device name directly from a file descriptor pointing to a character device. If it is unable to come up with a suitable name, these functions will return a NULL pointer.

devname() and **fdevname()** return the name stored in a static buffer which will be overwritten on subsequent calls. **devname_r()** and **fdevname_r()** take a buffer and length as argument to avoid this problem.

EXAMPLES

```
int fd;
struct stat buf;
```

```
char *name;

fd = open("/dev/tun");
fstat(fd, &buf);
printf("devname is /dev/%s\n", devname(buf.st_rdev, S_IFCHR));
printf("fdevname is /dev/%s\n", fdevname(fd));
```
