NAME

    proccontrol - Control some process execution aspects

SYNOPSIS

    proccontrol -m *mode* [**-s** *control*] [**-q**] **-p** *pid | command*

DESCRIPTION

    The **proccontrol** command modifies the execution parameter of existing process specified by the *pid* argument, or starts execution of the new program *command* with the execution parameter set for it.

    Which execution parameter is changed, selected by the mandatory parameter *mode*. Possible values for *mode* are:

    aslr   Control the Address Space Layout Randomization. Only applicable to the new process spawned.

    trace   Control the permission for debuggers to attach. Note that process is only allowed to enable tracing for itself, not for any other process.

    trapcap Controls the signalling of capability mode access violations.

    protmax

            Controls the implicit PROT_MAX application for mmap(2).

    nonewprivs

            Controls disabling the setuid and sgid bits for execve(2).

    wxmap

            Controls the write exclusive execute mode for mappings.

    kpti   Controls the KPTI enable, AMD64 only.

    la48   Control limiting usermode process address space to 48 bits of address, AMD64 only, on machines capable of 57-bit addressing.

    The *control* specifies if the selected *mode* should be enabled or disabled. Possible values are *enable* and *disable*, with the default value being *enable* if not specified. See procctl(2) for detailed description of each mode effects and interaction with other process control facilities.

    The **-q** switch makes the utility query and print the current setting for the selected mode. The **-q** requires

the query target process specification with **-p**.

EXIT STATUS

The **proccontrol** utility exits 0 on success, and >0 if an error occurs.

EXAMPLES

⊕   To disable debuggers attachment to the process 1020, execute
      proccontrol -m trace -s disable -p 1020

⊕   To execute the uniq(1) program in a mode where capability access violations cause SIGTRAP
delivery, do
      proccontrol -m trapcap uniq

⊕   To query the current ASLR enablement mode for the running process 1020, do
      proccontrol -m aslr -q -p 1020
